Machine learning leads mathematicians to unsolvable problem

Simple artificial-intelligence problem puts researchers up against a logical paradox discovered by famed mathematician Kurt Gödel.

Davide Castelvecchi
That sounds exciting . . .

But, when you read this piece in *Nature* about a paper in *Nature Machine Learning* . . .

The Continuum Hypothesis is a paradox . . .?!?

And there is confusion with Gödel’s First Incompleteness Theorem.

So, . . ., what gives?
What’s in the paper itself?

In one sentence:

the existence of a certain kind of learning function is equivalent to

\[ 2^\aleph_0 < \aleph_\omega \]

Almost what Cantor wrote:
“Durch ein Induktionsverfahren, auf dessen Darstellung wir hier
nicht näher eingehen, wird der Satz nahe gebracht, daß die Anzahl
der nach diesem Einteilungsprinzip sich ergebenden Klassen linearer
Mannigfaltigkeiten eine endliche und zwar, daß sie gleich Zwei ist.”
What’s in the paper?

In more detail.

The problem: find a method to pick a finite set that maximizes, within a certain tolerance, a certain expected value.

The difficulty: the probability distributions are unknown.

Approach: work with the family of finite subsets of the unit interval $\mathbb{I}$. 
An abstract learning function

Wanted: a function

\[ G : \bigcup_{k \in \mathbb{N}} \mathbb{I}^k \to \text{fin} (\mathbb{I}) \]

with certain properties.

Look at \( \mathbb{P} \), the family of all probability distributions on \( \mathbb{I} \) with finite support.
Every finite subset \( F \) has an expectation with respect to such a distribution.
We let \( \text{Opt}(\mathbb{P}) = \sup\{ \mathbb{E}_P(F) : F \in \text{fin}(\mathbb{I}) \} \).
The objective is to learn/guess(?) as well as possible.
An abstract learning function

$G$ is an $(\varepsilon, \delta)$-EMX learning function if there is an integer $d$ (depending on $\varepsilon$ and $\delta$) such that

$$\Pr_{S \sim P^d} \left[ \mathbb{E}_P (G(S)) \leq \text{Opt}(P) - \varepsilon \right] \leq \delta$$
An abstract learning function

Translation to (our kind of) combinatorics:
there is such a function with $\varepsilon = \delta = \frac{1}{3}$
if and only if
there is an $(m + 1) \to m$ monotone compression scheme, for some $m \in \mathbb{N}$
Monotone compression schemes

What is a $k \rightarrow l$ monotone compression scheme? A function $\eta : \mathbb{I}^l \rightarrow \text{fin}(\mathbb{I})$ such that for every $x \in \mathbb{I}^k$ there is a $y \in [x]^l$ such that $x \subseteq \eta(y)$.

We reformulate this.

In the above there is an implicit function $\sigma : \mathbb{I}^k \rightarrow \mathbb{I}^l$ with the property that

$$\sigma(x) \subseteq x \subseteq \eta(\sigma(x))$$
Monotone compression schemes

We only need $\sigma$!

There is an $k \rightarrow l$ monotone compression scheme if and only if there is a finite-to-one function $\sigma : \mathbb{I}^k \rightarrow \mathbb{I}^l$ such that $\sigma(x) \subseteq x$ for all $x$

‘only if’: use $\eta$; if $y \in \mathbb{I}^l$ then $\sigma(x) = y$ implies $x \subseteq \eta(y)$

‘if’: define $\eta$ by $\eta(y) = \bigcup\{x : \sigma(x) = y\}$
Where are the cardinals?

Here:

**Theorem**

Let $X$ be a set and $k \in \mathbb{N}$; there is a finite-to-one function $\sigma : [X]^{k+2} \to [X]^{k+1}$ such that $\sigma(x) \subseteq x$ for all $x$ if and only if $|X| \leq \aleph_k$.

And there you have it:
there is an $(m + 1) \to m$ monotone compression scheme for some $m$
if and only if $|\Pi| < \aleph_\omega$
An old result of Kuratowski’s

Theorem (Kuratowski 1951)

Let $X$ be a set and $k \in \mathbb{N}$; then $|X| \leq \aleph_k$ if and only if

$X^{k+2} = \bigcup_{i < k+2} A_i$, where for every $i < k + 2$ and every point

$\langle x_j : j < k + 2 \rangle$ in $X^{k+2}$ the set of points $y$ in $A_i$ that satisfy

$y_j = x_j$ for $j \neq i$ is finite; in Kuratowski’s words:

“A$_i$ is finite in the direction of the $i$th axis”.

For $k = 0$: look at $\mathbb{N}^2$.

$A_0 = \{ \langle m, n \rangle : m \leq n \}$ and $A_1 = \{ \langle m, n \rangle : m > n \}$. 
An old result of Kuratowski’s

For $k = 1$ this is already non-trivial:

to make $A_0$, $A_1$, and $A_2$ in $\omega_1^3$ choose, simultaneously, for every $\alpha \geq \omega_0$ a well-order $\prec_\alpha$ of $\alpha + 1$ in type $\omega$.

Exercise: for every $\alpha \geq \omega_0$ use $\prec_\alpha$ to write

$$(\alpha + 1)^2 = A_0(\alpha) \cup A_1(\alpha)$$

and manufacture $A_0$, $A_1$, and $A_2$ out of these sets.
There is a connection

We, generally, identify $[X]^n$ with

$$\{ x \in X^n : (i < j < n) \rightarrow (x_i < x_j) \}$$

(assuming $X$ has a linear order of course).

It is now quite easy to create our function $\sigma : [\omega_k]^{k+2} \rightarrow [\omega_k]^{k+1}$ from Kuratowski’s decomposition.
There is a connection

Without loss of generality the $A_i$ are pairwise disjoint.
Let $x \in [\omega_k]^{k+2}$, so $x = \langle x_i : i < k + 2 \rangle$ with
$(i < j < k + 2) \rightarrow (x_i < x_j)$.
Take the $i$ with $x \in A_i$ and let $\sigma(x) = x \setminus \{x_i\}$.
If $y \in [\omega_k]^{k+1}$ then for each $i < k + 2$ there are only finitely many $x$ in $A_i$ with $y = \sigma(x)$. 

There is a connection

Suppose $n > m$ and $\sigma : [\omega_{k+1}]^n \rightarrow [\omega_{k+1}]^m$ is finite-to-one and such that $\sigma(x) \subseteq x$ for all $x$.

The set $C$ of $\delta \in \omega_{k+1}$ that is closed under $\sigma^{-1}$ is closed and unbounded.

I mean: if $\delta \in C$ and $y \in [\delta]^m$ then $x \in [\delta]^n$ whenever $y = \sigma(x)$.

Take $\delta \in C$ with $\delta \geq \omega_k$.
Then $\varsigma : [\delta]^{n-1} \rightarrow [\delta]^{m-1}$, defined by

$$\varsigma(x) = \sigma(x \cup \{\delta\}) \setminus \{\delta\}$$

is finite-to-one and satisfies $\varsigma(x) \subseteq x$ for all $x$. 
Summary

We get the following

**Theorem**

Let $X$ be a set and $k \in \mathbb{N}$. Then the following are equivalent.

1. $|X| \leq \aleph_k$
2. $X^{k+2} = \bigcup_{i < k+2} A_i$, where for every $i < k + 2$ the set $A_i$ is finite in the direction of the $i$th axis
3. there is a $(k + 2) \to (k + 1)$ monotone compression scheme for $X$. 

Are there algorithms?

The functions in the proofs given above and in the paper are quite non-constructive as they involve blatant appeals to the Axiom of Choice.

How about algorithmic/definable/… functions?

Say, continuous, or Borel measurable.
High-brow answer

No.

If $\sigma : [\mathbb{P}]^{m+1} \rightarrow [\mathbb{P}]^m$ is a Borel measurable function that determines a compression scheme then after adding $\aleph_{\omega+1}$ Cohen reals its reinterpretation should still work, which it does not.
Elementary answer

Assume $\sigma : [I]^{m+1} \to [I]^m$ is a monotone compression scheme.

Exercise: show that if $\sigma$ is continuous there is a single $i$ such that $\sigma(x) = x \setminus \{x_i\}$ for all $x$ in $[I]^{m+1}$.

Exercise: show that if $\sigma$ is Borel measurable the above is almost true: there are an $x \in [I]^m$ and a non-meager set $A$ such that $x = \sigma(x \cup \{a\})$ for all $a \in A$.

In either case $\sigma$ is far from finite-to-one
Consequence

If the learning function from the beginning is Borel measurable then so is the compression scheme.

So to me this shows that that problem does not look so undecidable after all: there is no algorithm that works.
